[Proof YES/NO]	YES	

**【NAME OF DOCUMENT】 SPECIFICATION**

**【 TITLE OF THE INVENTION 】 CONTROL UNIT FOR INTERNAL COMBUSTION ENGINE**

**【WHAT IS CLAIMED IS】**

5           **【CLAIM 1】** A control unit for an internal combustion engine including a three way catalyst and an HC adsorbent on an exhaust side,

              wherein said control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of said three way catalyst when said internal combustion engine starts.

10           **【CLAIM 2】** A control unit for an internal combustion engine including a three way catalyst on an exhaust side,

              wherein control unit has a means for detecting completion of the evaporation of moisture in said three way catalyst directly or indirectly, and

              wherein control unit alternately controls the A/F between a rich state and a lean  
15 state in order to quicken the activation of said three way catalyst after the completion of the evaporation of moisture in said three way catalyst is detected.

**【CLAIM 3】** The control unit for an internal combustion engine according to claim 2,

              wherein the ignition time is retarded for the period until moisture in said three  
20 way catalyst evaporates directly after the start of said internal combustion engine.

**【CLAIM 4】** A control unit for an internal combustion engine including a three way catalyst on an exhaust side,

              wherein control unit has a means for detecting the temperature of said three way catalyst directly or indirectly, and

wherein control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of the three way catalyst when the temperature of said three way catalyst is a value within the fixed range.

5      **【CLAIM 5】** A control unit for an internal combustion engine including a three way catalyst on an exhaust side,

wherein control unit has a means for detecting the operating state of the internal combustion engine, and

10      wherein control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of the three way catalyst based on the operating state.

**【CLAIM 6】** A control unit for an internal combustion engine including a three way catalyst and an HC adsorbent on an exhaust side in the order,

wherein control unit has a means for detecting the temperature of said HC adsorbent directly or indirectly, and

15      wherein control unit alternately controls the A/F between a rich state and a lean state in order to change the temperature of said HC adsorbent.

**【CLAIM 7】** The control unit for an internal combustion engine according to claim 6,

20      wherein control unit alternately controls the A/F between a rich state and a lean state when the temperature of said HC adsorbent is within the fixed range.

**【CLAIM 8】** A control unit for an internal combustion engine including a catalyst which has the three way catalyst and HC adsorbent in the same carrier on an exhaust side,

wherein control unit alternately controls the A/F between a rich state and a lean

state in order to change the temperature of said HC adsorbent.

## **【DETAILED DESCRIPTION OF THE INVENTION】**

### **【0001】**

### **【TECHNICAL FIELD TO WHICH THE INVENTION BELONGS】**

5           The present invention relates to a control unit for an internal combustion engine, especially to a control unit for an internal combustion engine to activate quickly a three way catalyst when the internal combustion engine starts, and to do efficiently the adsorption and the purification of HC.

### **【0002】**

### **10           【PRIOR ART】**

          The demand of the work on the energy saving in the world scale and the environmental protection keeps strengthening more and more in the environment which surrounds the car in recent years, and the fuel cost restriction and the Emission Control, etc. have been reinforced.

15           In general, three way catalyst having the function of oxidizing HC and CO in the exhaust gas exhausted to the exhaust pipe by the internal combustion engine and reducing NOx to clear said Emission Control has been installed in the automobile engine.

          Although said three way catalyst can purify HC, CO, and NOx in exhaust gas  
20   at a temperature more than a fixed one, it cannot usually purify enough HC, CO, and NOx at a temperature below a fixed temperature.

### **【0003】**

          In general, an internal combustion engine is at low temperature when starting. Because the purification performance of exhaust gas is remarkably low for the period to

becoming of the three way catalyst more than a fixed temperature as shown in Fig.7 (Fig.7 shows an example of HC), it is important to activate the three way catalyst at the early stage when starting to decrease HC, CO, and Nox in exhaust gas. Therefore, a lot of the techniques have been proposed so far.

5           In the technology and according to the Japanese Patent Application Laid-Open No. 5-33705, by alternately supplying the rich exhaust and the lean exhaust to said three way catalyst; CO and HC including in the rich exhaust and O2 in the lean exhaust are made to react with each other, and the catalyst is warmed up with the heat of reaction.

【0004】

10       **【PROBLEMS TO BE SOLVED BY THE INVENTION】**

          Though in said technology CO and HC including in the rich exhaust and O2 in the lean exhaust are made to burn by alternately supplying the rich exhaust and the lean exhaust to said three way catalyst, All necessarily exhausted HC and CO does not burn, and are exhausted outside through the catalyst. Therefore, there is a problem that HC  
15   and CO is not improved though the object of warming up the catalyst can be achieved. Especially, HC deterioration when starting becomes a big problem by the restriction reinforcement of the exhaust gas in recent years.

【0005】

          The present invention was performed considering said problems.

20   An object of the present invention is to provide a control unit for an internal combustion engine in which the three way catalyst is activated at the early stage when the internal combustion engine starts, and the deterioration of components such as HC, CO, and NOx in exhaust gas from an internal combustion engine is reduced.

【0006】

## 【MEANS FOR SOLVING THE PROBLEMS】

A control unit for an internal combustion engine including a three way catalyst and an HC adsorbent on an exhaust side, wherein said control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of said three way catalyst when said internal combustion engine starts (Fig.1).

### 【0007】

The control unit for an internal combustion engine of the present invention configured like the above-mentioned can raise the temperature of the three way catalyst by alternately supplying rich exhaust and lean exhaust to the three way catalyst, and by the heat of reaction of CO, HC in the rich exhaust and O<sub>2</sub> in the lean exhaust. In addition, by installing an HC adsorbent in the downstream of the three way catalyst and by supplying the rich exhaust and the lean exhaust, the three way catalyst can be activated at the early stage without deteriorating the exhaust gas by adsorbing HC emitted from the downstream of the three way catalyst by using HC adsorbent.

### 【0008】

Moreover, a control unit for an internal combustion engine according to another embodiment of the present invention is characterized by a control unit for an internal combustion engine including a three way catalyst on an exhaust side, wherein control unit has a means for detecting completion of the evaporation of moisture in said three way catalyst directly or indirectly, and wherein control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of said three way catalyst after the completion of the evaporation of moisture in said three way catalyst is detected (see Fig.2).

Further, the ignition time is retarded for the period until moisture in said three

way catalyst evaporates directly after the start of said internal combustion engine.

【0009】

In the control unit for an internal combustion engine of the present invention configured like the above-mentioned, the reason for the supply of rich/lean exhaust to the three way catalyst is that the temperature of precious metals in the three way catalyst are raised. If the precious metals have been partially activated, the reaction proceeds further in that part, and the activation of precious metals in the catalyst is advanced continuously by the heat of reaction. The three way catalyst can be activated at the early stage without deteriorating the exhaust by supplying rich/lean exhaust after water in the three way catalyst evaporates, because the heat of reaction can be efficiently supplied to precious metals if there is no moisture in the three way catalyst. Moreover, the exhaust temperature is raised by making the ignition time retarded directly after the start, moisture in the catalyst evaporates promptly, and the supply of rich/lean exhaust is controlled at the early stage, because the activation time is shortened by time for water to evaporate short.

【0010】

Further, a control unit for an internal combustion engine according to a further embodiment of the present invention is characterized by a control unit for an internal combustion engine including a three way catalyst on an exhaust side, wherein control unit has a means for detecting the temperature of said three way catalyst directly or indirectly, and wherein control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of the three way catalyst when the temperature of said three way catalyst is a value within the fixed range (Fig.3).

【0011】

The control unit for an internal combustion engine of the present invention configured like the above-mentioned can estimate the evaporation of the moisture in the catalyst by directly or indirectly detecting the temperature of the catalyst, and control the supply rich/lean exhaust with a high degree of accuracy by setting the temperature of the catalyst to the value within the fixed range.

【0012】

Further, a control unit for an internal combustion engine according to a further embodiment of the present invention is characterized by a control unit for an internal combustion engine including a three way catalyst on an exhaust side, wherein control unit has a means for detecting the operating state of the internal combustion engine, and wherein control unit alternately controls the A/F between a rich state and a lean state in order to quicken the activation of the three way catalyst based on the operating state (Fig.4).

【0013】

The control unit for an internal combustion engine of the present invention configured like the above-mentioned can control the supply rich/lean exhaust with a higher degree of accuracy by estimating the temperature of the catalyst and estimating the evaporation of the moisture in the catalyst based on the operating state of the internal combustion engine, for instance, the time after the engine starts, the water temperature, total air flow rate after the engine starts and so on.

【0014】

Further, the control unit for an internal combustion engine according to a further embodiment of the present invention is characterized by a control unit for an internal combustion engine including a three way catalyst and an HC adsorbent on an

exhaust side in the order, wherein control unit has a means for detecting the temperature of said HC adsorbent directly or indirectly, and wherein control unit alternately controls the A/F between a rich state and a lean state in order to change the temperature of said HC adsorbent. The control unit alternately controls the A/F between a rich state and a lean state when the temperature of said HC adsorbent is within the fixed range (Fig.5).

【0015】

In the control unit for an internal combustion engine of the present invention configured like the above-mentioned, the HC adsorbent has the characteristic that HC is adsorbed at a temperature below a fixed one, and is desorbed at a temperature more than a fixed one because the HC adsorbent loses the adsorbent characteristic. In general, HC desorption temperature is lower than the activating temperature of the three way catalyst, the difference between these temperatures is large, and there is a temperature raise characteristic in which each phase of HC adsorbent, desorption, and purification becomes the best. And, the temperature of said three way catalyst is adjusted by controlling the supply of rich/lean exhaust appropriately with paying attention to the above-mentioned. As a result, it is possible to control so that the temperature raise characteristic of the HC adsorbent may become the best.

【0016】

Further, a control unit for an internal combustion engine according to a further embodiment of the present invention is characterized by a control unit for an internal combustion engine including a catalyst which has the three way catalyst and HC adsorbent in the same carrier on an exhaust side, wherein control unit alternately controls the A/F between a rich state and a lean state in order to change the temperature of said HC adsorbent (Fig.6).

【0017】

In the control unit for an internal combustion engine of the present invention configured like the above-mentioned, the temperature of the three way catalyst is raised by the heat of reaction of O<sub>2</sub> in the lean exhaust and CO, HC in the rich exhaust by alternately supplying the rich exhaust and the lean exhaust to the catalyst supported by the same carrier. In addition, HC separated from the three way catalyst is adsorbed by the HC adsorbent by supplying the rich exhaust and the lean exhaust. As a result, the exhaust gas is not deteriorated, and the three way catalyst is activated at the early stage. However, it is preferable that the temperature in the downstream of the catalyst is set such that the evaporation of the moisture in the three way catalyst is not completed but the adsorbed HC in HC adsorption catalyst begins to separate.

【0018】

#### 【EMBODIMENTS OF THE INVENTION】

Some embodiments of a control unit for an internal combustion engine of the present invention are explained in detail hereafter referring to the drawing.

【0019】

[A first embodiment]

Fig.8 shows the whole internal combustion engine system according to a first embodiment of the control unit for an internal combustion engine of the present invention.

Internal combustion engine 1 is configured of the internal combustion engine of the multi-cylinder type. In an air intake system, air from the outside passes air cleaner 19, flows into combustion chamber 9a in cylinder 9 through intake manifold 6. Although an amount of the inflow air is chiefly adjusted with throttle 3, the air amount

is adjusted with ISC valve 5 installed in air passage 4 for the by-pass at idling, and the engine speed of the internal combustion engine is controlled. Fuel injection valve 7 for each cylinder is installed in intake manifold 6. Sparking plug 8 is installed in cylinder 9 of each cylinder, and intake valve 29 and exhaust valve 30 are also arranged therein.

5     **【0020】**

Moreover, in an exhaust system, exhaust manifold 10 is connected to cylinder 9 of each cylinder, and three way catalyst 11 and HC adsorption catalyst 18 are arranged in the exhaust manifold 10 in the order. Air flow sensor 2 is arranged in intake manifold 6 of the air intake system, which detects an amount of the intake air. Crank angle sensor 10 15 outputs a signal every one degree of the rotation angle of the crankshaft. In throttle opening sensor 17 installed in electronic throttle 3, the opening of electronic throttle 3 is detected, and in water temperature sensor 14, the temperature of the cooling water for the internal combustion engine is detected.

**【0021】**

15         Each signal from air flow sensor 2, opening sensor 17 installed in throttle 3, crank angle sensor 15, and water temperature sensor 14 is sent to control unit 16. The operating state of internal combustion engine 1 is obtained from these sensor outputs, and the main manipulated variable of the ignition time and the basic injection amount of the fuel are calculated appropriately. Fuel injection amount calculated in control unit 16 20 is converted into a valve-open pulse signal and is sent to fuel injection valve 7 installed in the intake pipe of each cylinder. Therefore, fuel injection amount can be controlled every cylinder.

**【0022】**

Moreover, the predetermined ignition time is calculated in control unit 16, and

a driving signal is sent to sparking plug 8 so that it can be ignited at its ignition time. The fuel injected from fuel injection valve 7 flows into combustion chamber 9a of internal combustion engine 1, and forms the air-fuel mixture by being mixed with the air from intake manifold 6. The air-fuel mixture is exploded by the spark generated by sparking plug 8, and the energy generated at that time becomes the power source for internal combustion engine 1.

【0023】

The exhaust gas after explosion is sent to three way catalyst 11 through exhaust manifold 10 to purify HC, CO, and Nox. HC adsorption catalyst 18 has a three way characteristic inside, that is, the function of purifying the desorbed HC.

【0024】

A/F sensor 12 is installed between cylinder 9 of internal combustion engine 1 and three way catalyst 11, which has a linear output characteristic with respect to the oxygen concentration included in the exhaust gas. Because the relationship between the oxygen concentration included in the exhaust gas and the A/F is approximately linear, it is possible to detect the A/F by A/F sensor 12 which detects the oxygen concentration. Moreover, temperature sensor 13 is installed in the downstream of three way catalyst 11. Therefore, the detection of the temperature in the downstream of three way catalyst 11 is enabled.

In control unit 16, the A/F in the upstream of three way catalyst 11 is calculated from a signal of A/F sensor 12, and the amount of the fuel supplied to internal combustion engine 1 is controlled to become an A/F whose purification efficiency is the highest in three way catalyst 11.

【0025】

Fig. 9 shows the inside of the control unit (ECU) 16 shown in Fig.8. The output value of each sensor of air flow sensor 2, A/F sensor 12, temperature sensor 13, water temperature sensor 14, internal combustion engine speed sensor 15, and throttle valve opening sensor 17 is input in ECU 16, and after the signal processing such as noise rejection etc. is carried out in input circuit 23, the signal is sent to I/O port 24. The value of I/O port 24 is kept in RAM 22, and the operation processing is carried out in CPU20. Control program which describes the content of the operation processing is written in ROM 21 beforehand. The value which indicates the amount of each actuator operation calculated according to control program is kept in RAM 22. Then, it is sent to I/O port 24. An ON/OFF signal is set as an operation signal of sparking plug 8, in which it is turned on at a conduction state of the primary coil in ignition output circuit 25, and it is turned off at a non-conduction state of the primary coil. The ignition time is when the operation signal becomes turning-off from turning-on. The signal for the sparking plug set in I/O port 24 is amplified into enough energy necessary for combustion in ignition output circuit 25 and supplied to sparking plug 8. An ON/OFF signal is set as a driving signal of fuel injection valve 7, in which the ON/OFF signal is turned on at valve-open and turned off at valve-close. The driving signal is amplified into energy enough to open fuel injection valve 7 in fuel injection valve drive circuit 26, and sent to fuel injection valve 7.

20     【0026】

Fig.10 is a control block diagram showing the entire control of control unit 16 according to the embodiment shown in Fig. 9.

The control unit 16 comprises basic fuel injection amount calculation unit 31, A/F correction term calculation unit 32, #1 cylinder A/F correction amount calculation unit

33a, #2 cylinder A/F correction amount calculation unit 33b, #3 cylinder A/F correction amount calculation unit 33c, #4 cylinder A/F correction amount calculation unit 33d, and rich/lean control permission judgement part 34.

【0027】

5           When the rich/lean control is not permitted, the fuel injection amount for each cylinder is calculated so that the A/F for all cylinders may become a theoretical air-fuel ratio. When rich/lean control is permitted, the A/F for each cylinder is changed in the specified amount in order to activate three way catalyst 11 at the early stage by supplying the rich exhaust and the lean exhaust to the entrance of three way catalyst 11.

10           Hereinafter, each calculation unit of said control unit 16 will be explained in detail.

【0028】

1. Basic fuel injection amount calculation unit 31.

15           Fig.11 shows basic fuel injection amount calculation unit 31. The basic fuel injection amount calculation unit 31 calculates the fuel injection amount to achieve the target torque and the target A/F at the same time in an arbitrary operating condition based on an amount of the inflow air into internal combustion engine 1. Concretely, basic fuel injection amount  $T_p$  is calculated as shown in Fig.11. Here,  $K$  is a constant, which always make A/F adjust the theoretical A/F for the amount of the inflow air.

20           Further,  $Cyl$  indicates the number of cylinders of internal combustion engines 1, and the number of cylinders is 4 in this embodiment.

【0029】

2. A/F correction term calculation unit 32.

Fig.12 shows A/F correction term calculation unit 32. Here, A/F correction

term calculation unit 32 feedback-controls A/F based on the A/F detected by A/F sensor 12 so that the A/F of internal combustion engine 1 may take the theoretical A/F in an arbitrary operating condition. Concretely, A/F correction term  $L_{\alpha}$  is calculated from deviation  $D_{\text{tabf}}$  between the target A/F  $T_{\text{abf}}$  and the A/F  $R_{\text{abf}}$  detected by A/F sensor 5 by using the PID control as shown in Fig.12. A/F correction term  $L_{\alpha}$  is multiplied by above-mentioned basic fuel injection amount  $T_p$  in order to always keep A/F of internal combustion engine 1 to the theoretical A/F.

【0030】

3. Rich/lean control permission judgement part 34.

10 Fig.13 shows rich/lean control permission judgement part 34. The rich/lean control permission judgement part 34 performs the permission judgment of the rich/lean control. Concretely, it makes the rich/lean control permission flag to  $F_{\text{pRL}}=1$  and permits the rich/lean control if  $T_{\text{cn}} \geq T_{\text{cnL}}$ ,  $T_{\text{cn}} \leq T_{\text{cnH}}$ , and  $N_e \leq N_{\text{eRL}}$ , as shown in Fig.13. Otherwise, Rich/lean control is prohibited, and  $F_{\text{pRL}}=0$  is set.

15 Where,  $T_{\text{cn}}$  : downstream temperature of the three way catalyst, and  $N_e$  : engine speed of the internal combustion engine.

【0031】

It is preferable to set  $T_{\text{cnL}}$  to the temperature at which the evaporation of moisture in the three way catalyst is completed. The temperature becomes generally 20  $50^{\circ}\text{C}$ - $100^{\circ}\text{C}$ , which depends on the location of the sensor, etc. it is preferable to set  $T_{\text{cnH}}$  to the activation temperature of the three way catalyst. The temperature becomes  $250^{\circ}\text{C}$ - $400^{\circ}\text{C}$ , which depends on the catalyst performance. You should decide both values of  $T_{\text{cnL}}$  and  $T_{\text{cnH}}$  according to the performance of the real machine performance. Further, although it is assumed the method to detect the exhaust gas temperature in the

downstream of the catalyst in this embodiment, various methods of estimating from other operating condition of the internal combustion engine without measuring the temperature directly are proposed. Therefore, it is also possible to use them.

【0032】

5 4. #1 cylinder A/F correction amount calculation unit 33a.

Fig.14 shows the #1 cylinder A/F correction amount calculation unit 33a. In the #1 cylinder A/F correction amount calculation unit 33a, the amount of the A/F correction in the first cylinder is calculated. The #1 cylinder A/F correction amount Chos1 is set to 0 at rich/lean control permission flag FpRL=0, and fuel injection amount for each cylinder is calculated to obtain a theoretical A/F from the above-mentioned basic fuel injection amount Tp and A/F correction term Lalpha. The A/F of the first cylinder is changed in specified amount Kchos1 to supply the rich/lean exhaust to the entrance of three way catalyst 11 at rich/lean control permission flag FpRL=1. Concretely, the processing shown in Fig.14 is carried out. That is, it is assumed change amount Chos1=Kchos1 in the equivalence ratio of the #1 cylinder at rich/lean control permission flag FpRL=1, and assumed Chos1=0 at FpRL=0. It is desirable to set the value of Kchos1 from the performance of the degree of the temperature-rise of the three way catalyst and the exhaust according to the characteristic of internal combustion engine 1 and three way catalyst 11.

20 【0033】

5. #2 cylinder A/F correction amount calculation unit 33b.

Fig.15 shows the #2 cylinder A/F correction amount calculation unit 33b. In the #2 cylinder A/F correction amount calculation unit 33b, the amount of the A/F correction in the second cylinder is calculated. The #1 cylinder A/F correction amount

Chos2 is set to 0 at rich/lean control permission flag FpRL=0, and fuel injection amount for each cylinder is calculated to obtain a theoretical A/F from the above-mentioned basic fuel injection amount Tp and A/F correction term Lalpha. The A/F of the first cylinder is changed in specified amount Kchos2 to supply the rich/lean exhaust to the entrance of three way catalyst 11 at rich/lean control permission flag FpRL=1. Concretely, the processing shown in Fig.15 is carried out. That is, it is assumed change amount Chos2=Kchos2 in the equivalence ratio of the #2 cylinder at rich/lean control permission flag FpRL=1, and assumed Chos2=0 at FpRL=0. It is desirable to set the value of Kchos2 from the performance of the degree of the temperature-rise of the three way catalyst and the exhaust according to the characteristic of internal combustion engine 1 and three way catalyst 11.

【0034】

6. #3 cylinder A/F correction amount calculation unit 33c.

Fig.16 shows the #3 cylinder A/F correction amount calculation unit 33c. In the #3 cylinder A/F correction amount calculation unit 33c, the amount of the A/F correction in the third cylinder is calculated. The #3 cylinder A/F correction amount Chos3 is set to 0 at rich/lean control permission flag FpRL=0, and fuel injection amount for each cylinder is calculated to obtain a theoretical A/F from the above-mentioned basic fuel injection amount Tp and A/F correction term Lalpha. The A/F of the third cylinder is changed in specified amount Kchos3 to supply the rich/lean exhaust to the entrance of three way catalyst 11 at rich/lean control permission flag FpRL=1. Concretely, the processing shown in Fig.16 is carried out. That is, it is assumed change amount Chos3=Kchos3 in the equivalence ratio of the #3 cylinder at rich/lean control permission flag FpRL=1, and assumed Chos3=0 at FpRL=0. It is desirable to set the

value of Kchos1 from the performance of the degree of the temperature-rise of the three way catalyst and the exhaust according to the characteristic of internal combustion engine 1 and three way catalyst 11.

【0035】

5 7. #4 cylinder A/F correction amount calculation unit 33d.

Fig.16 shows the #4 cylinder A/F correction amount calculation unit 33d. In the #4 cylinder A/F correction amount calculation unit 33d, the amount of the A/F correction in the forth cylinder is calculated. The #4 cylinder A/F correction amount Chos4 is set to 0 at rich/lean control permission flag FpRL=0, and fuel injection amount  
10 for each cylinder is calculated to obtain a theoretical A/F from the above-mentioned basic fuel injection amount Tp and A/F correction term Lalpha. The A/F of the forth cylinder is changed in specified amount Kchos4 to supply the rich/lean exhaust to the entrance of three way catalyst 11 at rich/lean control permission flag FpRL=1. Concretely, the processing shown in Fig.14 is carried out. That is, it is assumed change  
15 amount Chos4=Kchos4 in the equivalence ratio of the #4 cylinder at rich/lean control permission flag FpRL=1, and assumed Chos4=0 at FpRL=0. It is desirable to set the value of Kchos1 from the performance of the degree of the temperature-rise of the three way catalyst and the exhaust according to the characteristic of internal combustion engine 1 and three way catalyst 11.

20 【0036】

[A second embodiment]

Fig.18 shows the entire system of the internal combustion engine according to the second embodiment of a control unit for an internal combustion engine of the present invention.

Because the second embodiment is the same as the first embodiment, excluding temperature sensor 13 not being provided, the explanation on other configuration is omitted.

【0037】

5            Fig.19 shows an internal configuration of control unit 16. Because its configuration is the same as one of the first embodiment, excluding the input terminal of temperature sensor 13 not being provided, the explanation on other configuration is omitted.

10           A control block diagram showing the entire control of control unit 16 according to this embodiment of Fig.19 is the same as one of the first embodiment of Fig.10, excluding the input signal of rich/lean control permission judgement part 34 is different. The control block diagram is not shown in figure and Fig.10 is referred instead.

【0038】

15           Control unit 16 of this embodiment comprises basic fuel injection amount calculation unit 31, A/F correction term calculation unit 32, #1 cylinder A/F correction amount calculation unit 33a, #2 cylinder A/F correction amount calculation unit 33b, #3 cylinder A/F correction amount calculation unit 33c, #4 cylinder A/F correction amount calculation unit 33d, and rich/lean control permission judgement part 34. When the  
20           rich/lean control is not permitted, control unit 16 calculates fuel injection amount for each cylinder so that the A/F for all cylinders may become a theoretical A/F. When the rich/lean control is permitted, the rich exhaust and the lean exhaust are supplied to the entrance of three way catalyst 11, the A/F for each cylinder is changed in the specified amount in order to activate the three way catalyst 11 at the early stage.

Hereafter, each calculation unit of control unit 16 will be explained in detail.

【0039】

1. Basic fuel injection amount calculation unit 31 and 2. A/F correction term calculation unit 32.

5           Because basic fuel injection amount calculation unit 31 and A/F correction term calculation unit 32 are the same as the first embodiment (Fig.11 and Fig.12), the explanation is omitted.

3. Rich/lean control permission judgement part 34

Fig.20 shows rich/lean control permission judgement part 34. In the rich/lean  
10 control permission judgement part 34, the permission judgment of rich/lean control is carried out. Concretely, it makes the rich/lean control permission flag to  $FpRL=1$  and permits the rich/lean control if water temperature at start  $\leq KTws$ , inflow air amount integrated value  $\leq Qasum$ , time  $TaftL$  after start or more, time  $TaftH$  after start or less, and  $Ne \leq NeRL$ , as shown in Fig.13. Otherwise, Rich/lean control is prohibited,  
15 and  $FpRL=0$  is set. Where,  $Ne$  : engine speed of the internal combustion engine.

it is preferable to perform the rich/lean control to the activation of three way catalyst 11 after the moisture in three way catalyst 11 evaporates as shown by the first embodiment. Said each parameter should be determined to suit the above condition,.

【0040】

20 4. #1 cylinder A/F correction amount calculation unit 33a; 5. #2 cylinder A/F correction amount calculation unit 33b; 6. #3 cylinder A/F correction amount calculation unit 33c; and 7. #4 cylinder A/F correction amount calculation unit 33d.

Because the #1 to #4 cylinder A/F correction amount calculation units 33a, 33b, 33c, and 33d are the same as the first embodiment (Fig.14-Fig.17), the explanation is

omitted.

【0041】

[A third embodiment]

Fig.21 shows the entire system of the internal combustion engine according to  
5 the third embodiment of a control unit for an internal combustion engine of the present invention.

Because the third embodiment is same as the first embodiment, excluding temperature sensor 27 being installed in the downstream of HC adsorption catalyst 18, the explanation on other configuration is omitted.

10 Fig.22 shows an internal configuration of control unit 16. Because its configuration is the same as one of the first embodiment, excluding the input terminal of temperature sensor 13 being added, the explanation on other configuration is omitted.

【0042】

Fig.23 is a control block diagram showing the entire control of control unit 16  
15 according to this embodiment shown in Fig.22.

Control unit 16 of this embodiment comprises basic fuel injection amount calculation unit 31, A/F correction term calculation unit 32, #1 cylinder A/F correction amount calculation unit 33a, #2 cylinder A/F correction amount calculation unit 33b, #3 cylinder A/F correction amount calculation unit 33c, #4 cylinder A/F correction amount  
20 calculation unit 33d, and rich/lean control permission judgement part 34.

【0043】

When the rich/lean control is not permitted, control unit 16 calculates fuel injection amount for each cylinder so that the A/F for all cylinders may become a theoretical A/F. When the rich/lean control is permitted, the rich exhaust and the lean

exhaust are supplied to the entrance of three way catalyst 11, in order to activate the three way catalyst 11 at the early stage or optimize the temperature-rise characteristic of HC adsorption catalyst 18.

Hereafter, each calculation unit of control unit 16 will be explained in detail.

5     **【0044】**

1. Basic fuel injection amount calculation unit 31 and 2. A/F correction term calculation unit 32.

Because basic fuel injection amount calculation unit 31 and A/F correction term calculation unit 32 are the same as the first embodiment (Fig.11 and Fig.12), the  
10     explanation is omitted.

3. Rich/lean control permission judgement part 34

Fig.24 shows rich/lean control permission judgement part 34. In the rich/lean control permission judgement part 34, the permission judgment of rich/lean control is carried out. The rich/lean control has two purposes, the temperature-rise of three way  
15     catalyst 11 and that of HC adsorption catalyst 18. Further, the permission condition is also divided into the temperature-rise control of the three way catalyst and that of HC adsorption catalyst roughly.

**【0045】**

Concretely, it makes three way catalyst temperature-rise control permission  
20     flag to  $FpCAT=1$  if  $Tcn \geq TcnL$ ,  $Tcn \leq TcnH$ , and  $Ne \leq Ne_{RL}$ . Otherwise,  $FpCAT=0$ . Where,  $Tcn$  : three way catalyst downstream temperature and  $Ne$  : engine speed of the internal combustion engine.

Further, it makes three way catalyst temperature-rise control permission flag to  $FpHC=1$  if  $Tcn2 \geq Tcn2L$  and  $Tcn2 \leq Tcn2H$ , Otherwise,  $FpHC=0$ . Where,  $Tcn$  : HC

adsorption catalyst downstream temperature.

It is preferable to set TcnL to the temperature at which the evaporation of moisture in the three way catalyst is completed. The temperature becomes generally 50°C-100°C, which depends on the location of the sensor, etc.

5     **【0046】**

It is preferable to set TcnH to the activation temperature of the three way catalyst. The temperature becomes 250°C-400°C, which depends on the catalyst performance. It is preferable to set Tcn2L to the temperature at which the adsorbed HC of the HC adsorption catalyst starts to be desorbed. The temperature becomes generally  
10   100°C-200°C, which depends on the location of the sensor, etc.

Further, it is preferable to set Tcn2H to the activation temperature of the three way catalyst in the HC adsorption catalyst 18. The temperature becomes 250°C-400°C, which depends on the catalyst performance. You should decide the values of TcnL, TcnH, Tcn2L and Tcn2H according to the performance of the real machine performance.

15    **【0047】**

4. #1 cylinder A/F correction amount calculation unit 33a; 5. #2 cylinder A/F correction amount calculation unit 33b; 6. #3 cylinder A/F correction amount calculation unit 33c; and 7. #4 cylinder A/F correction amount calculation unit 33d.

Because the #1 to #4 cylinder A/F correction amount calculation units 33a, 33b,  
20   33c, and 33d are the same as the first embodiment (Fig.14-Fig.17), the explanation is omitted.

**【0048】**

Although it is assumed the specification which raises temperature up to the temperature to which three way performance in HC adsorption catalyst 18 are activated

at the quickest velocity when the adsorbed HC in HC adsorption catalyst 18 starts to desorb in this embodiment, actually, it is also good to control in feedback based on the output of temperature sensor 27 according to the best temperature-rise curve. In this case, the temperature of HC adsorption catalyst 18 is adjusted by repeating an ON/OFF state of rich/lean control.

【0049】

[A fourth embodiment]

Fig.25 shows the entire system of the internal combustion engine according to the fourth embodiment of a control unit for an internal combustion engine of the present invention.

Catalyst 28 is a catalyst in which the HC adsorbent and the three way catalyst are supported by the same carrier. Because the configuration except the catalyst 28 is the same as the first embodiment, the explanation of other configuration is omitted.

【0050】

The Control in the control unit for an internal combustion engine according to this embodiment is the same as that in the first embodiment.

However, it is preferable to set a set temperature  $T_{cnH}$  in the downstream of the catalyst not to the temperature at which the evaporation of moisture in the three way catalyst is completed, but to the temperature at which the adsorbed HC of the HC adsorption catalyst starts to be desorbed. The temperature becomes generally 100°C -200°C, which depends on the location of the sensor, etc.

Actually, as described in the first embodiment, it is also good to control in feedback based on the output of temperature sensor 13 according to the best temperature-rise curve. In this case, the temperature of HC adsorption catalyst is

adjusted by repeating an ON/OFF state of rich/lean control.

【0051】

[A fifth embodiment]

Fig.26 is a control block diagram showing the entire control of control unit 16 according to the fifth embodiment of the present invention.

The control unit 16 comprises basic fuel injection amount calculation unit 31, A/F correction term calculation unit 32, #1 cylinder A/F correction amount calculation unit 33a, #2 cylinder A/F correction amount calculation unit 33b, #3 cylinder A/F correction amount calculation unit 33c, #4 cylinder A/F correction amount calculation unit 33d, rich/lean control permission judgement part 34 and ignition time calculation unit 35.

Because control unit 16 is the same as the first embodiment excluding ignition time calculation unit 35 being provided, the explanation is omitted.

【0052】

Control unit 16 of the internal combustion engine according to this embodiment has the purposes, to evaporate the moisture in three way catalyst 11 at the early stage and to heighten an effect of the rich/lean control. The retard is put at the ignition time when internal combustion engine 1 is started. Moreover, when the rich/lean control is not permitted, a fuel injection amount of each cylinder is calculated so that the A/F of all cylinders may become a theoretical A/F. When the rich/lean control is permitted, the A/F of each cylinder is changed in the specified amount to activate three way catalyst 11 at the early stage by supplying the rich exhaust and the lean exhaust to the entrance of three way catalyst 11.

Hereinafter, each calculation unit of said control unit 16 will be explained in

detail.

【0053】

1. Basic fuel injection amount calculation unit 31; 2. A/F correction term calculation unit 32; 3. Rich/lean control permission judgement part 34; 4. #1 cylinder A/F correction amount calculation unit 33a; 5. #2 cylinder A/F correction amount calculation unit 33b; 6. #3 cylinder A/F correction amount calculation unit 33c; 7. #4 cylinder A/F correction amount calculation unit 33d.

Because basic fuel injection amount calculation unit 31, A/F correction term calculation unit 32, rich/lean control permission judgement part 34, and #1 to #4 cylinder A/F correction amount calculation units 33a, 3b, 33c and 33d are the same as the first embodiment (Fig.11-Fig.17), the explanation is omitted.

【0054】

8. Ignition time calculation unit

Fig.27 shows ignition time calculation unit 35. In the ignition time calculation unit 35, the permission judgment of rich/lean control is performed.

Final ignition time  $ADV_f$  is calculated according to  $ADV_f = ADV_b - ADV_{RTD}$  as shown in Fig.27. Where,  $ADV_b$  : basic ignition time and  $ADV_{RTD}$  : ignition time retard amount.

Basic ignition time  $ADV_b$  is obtained with reference to basic ignition time  $Map_{ADV_b}$  from basic fuel injection amount  $T_p$  and internal combustion engine speed  $N_e$ .

【0055】

Ignition time retard amount  $ADV_{RTD}$  is  $AD_{RTD} = K \cdot ADV_{RTD}$  if retard control permission flag  $F_{pRTD} = 1$  of the ignition time, and  $ADV_{RTD} = 0$  if  $F_{pRTD} = 0$ . Retard control permission flag  $F_{pRTD}$  of the ignition time assumes  $F_{pRTD} = 1$  when three way

catalyst downstream temperature  $T_{cn}$  is  $T_{cn} \geq T_{cnL3}$ ,  $T_{cn} \leq T_{cnH3}$ , and  $N_e \geq N_{eRTD}$ , and the retard is performed. Otherwise,  $F_{pRTD}=0$ , and the retard is not performed.

【0056】

Because one of the purposes of this embodiment is to evaporate promptly the  
5 moisture in three way catalyst 11, it is preferable to set  $T_{cnL3}$  to at least 50°C or less.  
Further, it is preferable to set  $T_{cnH3}$  so that the maximum effect may be achieved in the  
rich/lean control by setting the activation temperature of the three way catalyst as the  
maximum value. It is preferable to set retard amount  $KADV_{RTD}$  to the retard limit  
determined according to the stability of the internal combustion engine. and it is  
10 determined according to the performance of the internal combustion engine.  
Further, basic ignition time map  $MapADV_b$  is determined according to the performance  
of the internal combustion engine to become a so-called MBT.

Although the present invention has been described in connection with five  
embodiments, the present invention should not be understood as limited to the specific  
15 embodiment set out above, and it should be understood that the foregoing and various  
other changes in design may be made therein and thereto, without departing from the  
spirit and scope of the present invention.

【0057】

【EFFECTS OF THE INVENTION】

20 Because the control unit for an internal combustion engine according to the  
present invention does not deteriorate the exhaust when starting, and be able to activate  
the three way catalyst at the early stage as understood from the above-mentioned  
explanation. Therefore, HC, CO, and NO<sub>x</sub>, etc. from the exhaust gas can be greatly  
decreased.

**【NAME OF DOCUMENT】 ABSTRACT**

**【ABSTRACT】**

**【PROBLEMS】** To provide a control unit for an internal combustion engine which can activate the three way catalyst at the early stage, and can lessen the deterioration of the exhaust in an internal combustion engine such as HC, CO, and NO<sub>x</sub>,  
5 etc. from the exhaust gas when starting

**【SOLUTION MEANS】** A control unit for an internal combustion engine which provides with three way catalyst and HC adsorbent on an exhaust side, wherein the control unit alternately controls the A/F between a rich state and a lean state in order  
10 to quicken the activation of said three way catalyst when said internal combustion engine starts.
